Homework 3: Static Analysis

http://d3s.mff.cuni.cz

Pavel Parízek
Design and implement a static analysis that finds whether the values of all object fields and local variables (of an integer type) stay in a given range

- Value of any variable cannot exceed the upper bound and cannot fall below the lower bound
- The range will be defined by the user as a configuration parameter of the analysis
  - For the purpose of this homework, it can be explicitly defined using constants in the procedure `main`
- Consider only fields and variables declared in application classes
  - You can ignore those declared in libraries
- Hint: note that you can have multiple elements of a bit-vector associated with every local variable (e.g., each bit representing one predicate about the variable)

Use the WALA library for implementation
Task 2

- Create some example programs to
  - Demonstrate your static analysis
  - Test its design and implementation
Task 3

- Test various configurations of your analysis
  - For example, different numbers of bits dedicated to each variable or field

- Document your solution (analysis design, etc)

- Discuss precision-performance trade-offs
  - All you identify during experiments
Organization

- Deadline: **25.5.2018**

- Submission
  - E-mail: parizek@d3s.mff.cuni.cz
