 Iterator & for cycle

• for (Object o : foo)
  – can be used if foo is an array or foo can be iterated
  – how to achieve it?
    • implement the java.lang.Iterable interface

• Iterable has a single method
  java.util.Iterator iterator()

• methods of the Iterator interface
  – boolean hasNext()
  – Object next()
  – void remove()

• the iterator typically implemented as an anonymous inner class

• in reality, the Iterator is generic, i.e. Iterator<T>
  – we will ignore it for now
public class MyArrayWithIterator implements Iterable {
    private Object[] arr = new Object[5];
    private int s = 0;

    public int size() {
        return s;
    }

    public void add(Object o) {
        ...
        arr[s++] = o;
        ...
    }

    public Iterator iterator() {
        return new Iterator() {
            private int index = 0;
            public boolean hasNext() {
                return index < s;
            }
            public Object next() {
                return arr[index++];
            }
            public void remove() {
                throw new UnsupportedOperationException();
            }
        };
    }
}

- since Java 8, remove() is default
- the implementation throws this exception
Assignment 1

• create the interface MyCollection with methods
  - void add(Object o)
  - Object get(int i)
  - void remove(Object o)
  - void remove(int i)
  - int size()

• create an implementation of MyCollection
  - use an array, which is reallocated if needed
  - handle all error states by exceptions
    • access out of bounds of the array

• add the iterator (see previous slides)
Assignment 2

- create a class representing a balanced binary search tree (e.g., AVL, RB, or any other)
  - for the \texttt{int} type
- add the iterator that iterates the tree from the smallest element till biggest one
- create a program, which uses the tree and loads data from arguments of the command-line
  - use \texttt{Integer.parseInt(String s)} to transform \texttt{String} into \texttt{int}
    - do not forget to handle exceptions the method throws in a case, the string cannot be transformed

- think how to update the tree in order it can be defined with the \texttt{Object} type
  - i.e. how to achieve that tree elements are comparable
  - implement it
Tests...
Test 1

• What is printed out – true or false

```java
public class Test01 {
    public static void main(String[] argv) {
        System.out.println(test());
    }

    public static boolean test() {
        try {
            return true;
        } finally {
            return false;
        }
    }
}
```

The example based on code from J. Bloch, N. Gafter: Java Puzzlers
Test 2

• What is printed out?

```java
public class Test02 {

    public static void main(String[] argv) {
        try {
            System.out.println("Hello world!");
            System.exit(0);
        } finally {
            System.out.println("Goodbye");
        }
    }
}
```

The example based on code from J. Bloch, N. Gafter: Java Puzzlers
Test 3

- What is printed out

```java
public class ParamsTest {
    public ParamsTest(Object o) {
        System.out.println("ParamsTest(Object o)");
    }
    public ParamsTest(long[] a) {
        System.out.println("ParamsTest(long[] a)");
    }
    public static void main(String[] argv) {
        new ParamsTest(null);
    }
}

- A cannot be compiled
- B ParamsTest(Object o)
- C ParamsTest(long[] a)
```
Test 3

● C is correct answer

● Why?
  – Searching a method/constructor
    • based on the actual parameters, all the methods/constructors that can be used, are selected
    • from the selected methods/constructors, the most specific one is selected based on the formal parameters
  – `ParamsTest(long[] a)` is more specific than `ParamTest(Object o)`
    • everything, that can assigned to `long[] a` can be also assigned to `Object`
    • but it is not true vice-versa
Test 4

- What is printed out

```java
class A {
    public static void foo() {
        System.out.println("foo");
    }
}
class B extends A {
    public static void foo() {
        System.out.println("bar");
    }
}
```

- A foo bar
- B foo foo
- C bar bar
- D something else

```java
public class OverloadTest {
    public static void main(String[] argv) {
        A a = new A();
        A b = new B();
        a.foo();
        b.foo();
    }
}
```
Test 4

- B is correct
- static methods are not virtual
