Preamble

This document is in the Ratified state

No changes are allowed. Any desired or needed changes can be the subject of a follow-on new extension. Ratified extensions are never revised.

Contributors to all versions of the spec in alphabetical order:

It is licensed under the Creative Commons Attribution 4.0 International License (CC-BY 4.0). The full license text is available at creativecommons.org/licenses/by/4.0/.

The latest version of this document can be found here: github.com/riscv-non-isa/riscv-elf-psabi-doc.

This specification is written in collaboration with the development communities of the major open-source toolchain and operating system communities, and as such specifies what has been agreed upon and implemented. As a result, any changes to this specification that are not backwards-compatible would break ABI compatibility for those toolchains, which is not permitted unless for features explicitly marked as experimental, and so will not be made unless absolutely necessary, regardless of whether the specification is a pre-release version, ratified version or anything in between. This means any version of this specification published at the above link can be regarded as stable in the technical sense of the word (but not necessarily in the official RISC-V International specification state meaning), with the official specification state being an indicator of the completeness, clarity and general editorial quality of the specification.
Introduction

This specification provides the processor-specific application binary interface document for RISC-V.

This specification consists of the following three parts:

• Calling convention
• ELF specification
• DWARF specification

A future revision of this ABI will include a canonical set of mappings for memory model synchronization primitives.
# Terms and Abbreviations

This specification uses the following terms and abbreviations:

<table>

</tr>
<tr>
<td>x28 - x31</td>
<td>t3 - t6</td>
<td>Temporary registers</td>
<td>No</td>
</tr>
</tbody>
</table>

In the standard ABI, procedures should not modify the integer registers tp and gp, because signal handlers may rely upon their values.

The presence of a frame pointer is optional. If a frame pointer exists, it must reside in x8 (s0); the register remains callee-saved.

1.2. Floating-point Register Convention

Table 2. Floating-point register convention

<table>
<thead>

<td>Temporary registers</td>
<td>No</td>
</tr>
</tbody>
</table>

*: Floating-point values in callee-saved registers are only preserved across calls if they are no larger than the width of a floating-point register in the targeted ABI. Therefore, these registers can always be considered temporaries if targeting the base integer calling convention.

The Floating-Point Control and Status Register (fcsr) must have thread storage duration in accordance with C11 section 7.6 "Floating-point environment <fenv.h>". 
1.3. Vector Register Convention

Table 3. Vector register convention

<table>
<thead>
<tr>

<td>No</td>
</tr>
<tr>
<td>vxsat</td>
<td>Vector fixed-point saturation flag register</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Vector registers are not used for passing arguments or return values; we intend to define a new calling convention variant to allow that as a future software optimization.

The \texttt{vxrm} and \texttt{vxsat} fields of \texttt{vcsr} are not preserved across calls and their values are unspecified upon entry.

Procedures may assume that \texttt{vstart} is zero upon entry. Procedures may assume that \texttt{vstart} is zero upon return from a procedure call.

Application software should normally not write \texttt{vstart} explicitly. Any procedure that does explicitly write \texttt{vstart} to a nonzero value must zero \texttt{vstart} before either returning or calling another procedure.
Chapter 2. Procedure Calling Convention

This chapter defines standard calling conventions, and describes how to pass parameters and return values.

Functions must follow the register convention defined in calling convention: the contents of any register without specifying it as an argument register in the calling convention are unspecified upon entry, and the content of any register without specifying it as a return value register or callee-saved in the calling convention are unspecified upon exit, the contents of all callee-saved registers must be restored to what was set on entry, and the contents of any fixed registers like gp and tp never change,

Calling convention for big-endian is NOT included in this specification yet, we intend to define that in future version of this specification.

2.1. Integer Calling Convention

The base integer calling convention provides eight argument registers, a0-a7, the first two of which are also used to return values.

Scalars that are at most XLEN bits wide are passed in a single argument register, or on the stack by value if none is available. When passed in registers or on the stack, integer scalars narrower than XLEN bits are widened according to the sign of their type up to 32 bits, then sign-extended to XLEN bits. When passed in registers or on the stack, floating-point types narrower than XLEN bits are widened to XLEN bits, with the upper bits undefined.

Scalars that are 2×XLEN bits wide are passed in a pair of argument registers, with the low-order XLEN bits in the lower-numbered register and the high-order XLEN bits in the higher-numbered register. If no argument registers are available, the scalar is passed on the stack by value. If exactly one register is available, the low-order XLEN bits are passed in the register and the high-order XLEN bits are passed on the stack.

Scalars wider than 2×XLEN bits are passed by reference and are replaced in the argument list with the address.

Aggregates whose total size is no more than XLEN bits are passed in a register, with the fields laid out as though they were passed in memory. If no register is available, the aggregate is passed on the stack. Aggregates whose total size is no more than 2×XLEN bits are passed in a pair of registers; if only one register is available, the first XLEN bits are passed in a register and the remaining bits are passed on the stack. If no registers are available, the aggregate is passed on the stack. Bits unused due to padding, and bits past the end of an aggregate whose size in bits is not divisible by XLEN, are undefined.

Aggregates or scalars passed on the stack are aligned to the greater of the type alignment and XLEN bits, but never more than the stack alignment.

Aggregates larger than 2×XLEN bits are passed by reference and are replaced in the argument list with the address, as are C++ aggregates with nontrivial copy constructors, destructors, or vtables.
Empty structs or union arguments or return values are ignored by C compilers which support them as a non-standard extension. This is not the case for C++, which requires them to be sized types.

Bitfields are packed in little-endian fashion. A bitfield that would span the alignment boundary of its integer type is padded to begin at the next alignment boundary. For example, `struct { int x : 10; int y : 12; }` is a 32-bit type with `x` in bits 9-0, `y` in bits 21-10, and bits 31-22 undefined. By contrast, `struct { short x : 10; short y : 12; }` is a 32-bit type with `x` in bits 9-0, `y` in bits 27-16, and bits 31-28 and bits 15-10 undefined.

Bitfields may be larger than its integer type, bits excess than its integer type will treat as padding bits, then padding to begin at the next alignment boundary. For example `struct { char x : 9; char y; }` is a 24 byte type with `x` in bits 7-0, `y` in bit 23-16, and bits 15-8 undefined, `struct { char x : 9; char y : 2 }` is a 16-bit type with `x` in bits 7-0, `y` in bit 10-9, and bit 8, bits 15-11 is undefined.

Arguments passed by reference may be modified by the callee.

Floating-point reals are passed the same way as aggregates of the same size; complex floating-point numbers are passed the same way as a struct containing two floating-point reals. (This constraint changes when the integer calling convention is augmented by the hardware floating-point calling convention.)

In the base integer calling convention, variadic arguments are passed in the same manner as named arguments, with one exception. Variadic arguments with 2×XLEN-bit alignment and size at most 2×XLEN bits are passed in an aligned register pair (i.e., the first register in the pair is even-numbered), or on the stack by value if none is available. After a variadic argument has been passed on the stack, all future arguments will also be passed on the stack (i.e. the last argument register may be left unused due to the aligned register pair rule).

Values are returned in the same manner as a first named argument of the same type would be passed. If such an argument would have been passed by reference, the caller allocates memory for the return value, and passes the address as an implicit first parameter.

There is no requirement that the address be returned from the function and so software should not assume that a0 will hold the address of the return value on return.

The stack grows downwards (towards lower addresses) and the stack pointer shall be aligned to a 128-bit boundary upon procedure entry. The first argument passed on the stack is located at offset zero of the stack pointer on function entry; following arguments are stored at correspondingly higher addresses.

In the standard ABI, the stack pointer must remain aligned throughout procedure execution. Non-standard ABI code must realign the stack pointer prior to invoking standard ABI procedures. The operating system must realign the stack pointer prior to invoking a signal handler; hence, POSIX signal handlers need not realign the stack pointer. In systems that service interrupts using the interruptee's stack, the interrupt service routine must realign the stack pointer if linked with any code that uses a non-standard stack-alignment discipline, but need not realign the stack pointer if all code adheres to the standard ABI.
Procedures must not rely upon the persistence of stack-allocated data whose addresses lie below the stack pointer.

Registers s0-s11 shall be preserved across procedure calls. No floating-point registers, if present, are preserved across calls. (This property changes when the integer calling convention is augmented by the hardware floating-point calling convention.)

2.2. Hardware Floating-point Calling Convention

The hardware floating-point calling convention adds eight floating-point argument registers, fa0-fa7, the first two of which are also used to return values. Values are passed in floating-point registers whenever possible, whether or not the integer registers have been exhausted.

The remainder of this section applies only to named arguments. Variadic arguments are passed according to the integer calling convention.

ABI_FLEN refers to the width of a floating-point register in the ABI. The ABI_FLEN must be no wider than the ISA's FLEN. The ISA might have wider floating-point registers than the ABI.

For the purposes of this section, "struct" refers to a C struct with its hierarchy flattened, including any array fields. That is, struct { struct { float f[1]; } g[2]; } and struct { float f; float g; } are treated the same. Fields containing empty structs or unions are ignored while flattening, even in C++, unless they have nontrivial copy constructors or destructors. Fields containing zero-length bit-fields are ignored while flattening. Attributes such as aligned or packed do not interfere with a struct's eligibility for being passed in registers according to the rules below, i.e. struct { int i; double d; } and struct __attribute__((__packed__)) { int i; double d } are treated the same, as are struct { float f; float g; } and struct { float f; float g __attribute__ ((aligned (8))) }.

A real floating-point argument is passed in a floating-point argument register if it is no more than ABI_FLEN bits wide and at least one floating-point argument register is available. Otherwise, it is passed according to the integer calling convention. When a floating-point argument narrower than FLEN bits is passed in a floating-point register, it is 1-extended (NaN-boxed) to FLEN bits.

A struct containing just one floating-point real is passed as though it were a standalone floating-point real.

A struct containing two floating-point reals is passed in two floating-point registers, if neither real is more than ABI_FLEN bits wide and at least two floating-point argument registers are available. (The registers need not be an aligned pair.) Otherwise, it is passed according to the integer calling convention.

A complex floating-point number, or a struct containing just one complex floating-point number, is passed as though it were a struct containing two floating-point reals.

A struct containing one floating-point real and one integer (or bitfield), in either order, is passed in a floating-point register and an integer register, provided the floating-point real is no more than ABI_FLEN bits wide and the integer is no more than XLEN bits wide, and at least one floating-point argument register and at least one integer argument register is available. If the struct is passed in this manner, and the integer is narrower than XLEN bits, the remaining bits are unspecified. If the
struct is not passed in this manner, then it is passed according to the integer calling convention.

Unions are never flattened and are always passed according to the integer calling convention.

Values are returned in the same manner as a first named argument of the same type would be passed.

Floating-point registers fs0-fs11 shall be preserved across procedure calls, provided they hold values no more than ABI_FLEN bits wide.

### 2.3. ILP32E Calling Convention

RV32E is not a ratified base ISA and so we cannot guarantee the stability of ILP32E, in contrast with the rest of this document. This documents the current implementation in GCC as of the time of writing, but may be subject to change.

The ILP32E calling convention is designed to be usable with the RV32E ISA. This calling convention is the same as the integer calling convention, except for the following differences. The stack pointer need only be aligned to a 32-bit boundary. Registers x16-x31 do not participate in the calling convention, so there are only six argument registers, a0-a5, only two callee-saved registers, s0-s1, and only three temporaries, t0-t2.

If used with an ISA that has any of the registers x16-x31 and f0-f31, then these registers are considered temporaries.

The ILP32E calling convention is not compatible with ISAs that have registers that require load and store alignments of more than 32 bits. In particular, this calling convention must not be used with the D ISA extension.

### 2.4. Named ABIs

This specification defines the following named ABIs:

**ILP32**

Integer calling-convention only, hardware floating-point calling convention is not used (i.e. ELFCLASS32 and EF_RISCV_FLOAT_ABI_SOFT).

**ILP32F**

ILP32 with hardware floating-point calling convention for ABI_FLEN=32 (i.e. ELFCLASS32 and EF_RISCV_FLOAT_ABI_SINGLE).

**ILP32D**

ILP32 with hardware floating-point calling convention for ABI_FLEN=64 (i.e. ELFCLASS32 and EF_RISCV_FLOAT_ABI_DOUBLE).

**ILP32E**

ILP32E calling-convention only, hardware floating-point calling convention is not used (i.e. ELFCLASS32, EF_RISCV_FLOAT_ABI_SOFT, and EF_RISCV_RVE).
LP64

Integer calling-convention only, hardware floating-point calling convention is not used (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_SOFT).

LP64F

LP64 with hardware floating-point calling convention for ABI_FLEN=32 (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_SINGLE).

LP64D

LP64 with hardware floating-point calling convention for ABI_FLEN=64 (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_DOUBLE).

LP64Q

LP64 with hardware floating-point calling convention for ABI_FLEN=128 (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_QUAD).

The ILP32* ABIs are only compatible with RV32* ISAs, and the LP64* ABIs are only compatible with RV64* ISAs. A future version of this specification may define an ILP32 ABI for the RV64 ISA, but currently this is not a supported operating mode.

The *F ABIs require the *F ISA extension, the *D ABIs require the *D ISA extension, and the LP64Q ABI requires the Q ISA extension.

---

**2.5. Default ABIs**

While various different ABIs are technically possible, for software compatibility reasons it is strongly recommended to use the following default ABIs for specific architectures:

- **on RV32G**  ILP32D
- **on RV64G**  LP64D

---

Although RV64GQ systems can technically use LP64Q, it is strongly recommended to use LP64D on general-purpose RV64GQ systems for compatibility with standard RV64G software.

This means code targeting the Zfinx extension always uses the ILP32, ILP32E or LP64 integer calling-convention only ABIs as there is no dedicated hardware floating-point register file.
Chapter 3. Calling Convention for System Calls

The calling convention for system calls does not fall within the scope of this document. Please refer to the documentation of the RISC-V execution environment interface (e.g OS kernel ABI, SBI).
Chapter 4. C/C++ type details

4.1. C/C++ type sizes and alignments

There are two conventions for C/C++ type sizes and alignments.

ILP32, ILP32F, ILP32D, and ILP32E

Use the following type sizes and alignments (based on the ILP32 convention):

<table>
<thead>
<tr>
<th>Type</th>
<th>Size (Bytes)</th>
<th>Alignment (Bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool/_Bool</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>char</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>short</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>int</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>long</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>long long</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>void *</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>_Float16</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>float</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>double</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>long double</td>
<td>16</td>
<td>16</td>
</tr>
<tr>
<td>float _Complex</td>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>double _Complex</td>
<td>16</td>
<td>8</td>
</tr>
<tr>
<td>long double _Complex</td>
<td>32</td>
<td>16</td>
</tr>
</tbody>
</table>

LP64, LP64F, LP64D, and LP64Q

Use the following type sizes and alignments (based on the LP64 convention):

<table>
<thead>
<tr>
<th>Type</th>
<th>Size (Bytes)</th>
<th>Alignment (Bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool/_Bool</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>char</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>short</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>int</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>long</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>Type</td>
<td>Size (Bytes)</td>
<td>Alignment (Bytes)</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>long long</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>_int128</td>
<td>16</td>
<td>16</td>
</tr>
<tr>
<td>void *</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>_Float16</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>float</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>double</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>long double</td>
<td>16</td>
<td>16</td>
</tr>
<tr>
<td>float _Complex</td>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>double _Complex</td>
<td>16</td>
<td>8</td>
</tr>
<tr>
<td>long double _Complex</td>
<td>32</td>
<td>16</td>
</tr>
</tbody>
</table>

The alignment of `max_align_t` is 16.

`CHAR_BIT` is 8.

Structs and unions are aligned to the alignment of their most strictly aligned member. The size of any object is a multiple of its alignment.

### 4.2. C/C++ type representations

`char` is unsigned.

Booleans (`bool/_Bool`) stored in memory or when being passed as scalar arguments are either 0 (false) or 1 (true).

A null pointer (for all types) has the value zero.

\_Float16 is as defined in the C ISO/IEC TS 18661-3 extension.

\_Complex types have the same layout as a struct containing two fields of the corresponding real type (`float`, `double`, or `long double`), with the first member holding the real part and the second member holding the imaginary part.

### 4.3. va_list, va_start, and va_arg

The `va_list` type is `void*`. A callee with variadic arguments is responsible for copying the contents of registers used to pass variadic arguments to the vararg save area, which must be contiguous with arguments passed on the stack. The `va_start` macro initializes its `va_list` argument to point to the start of the vararg save area. The `va_arg` macro will increment its `va_list` argument according to the size of the given type, taking into account the rules about 2×XLEN aligned arguments being passed in "aligned" register pairs.
Appendix A: Linux-specific ABI

This section of the RISC-V calling convention specification only applies to Linux-based systems.

In order to ensure compatibility between different implementations of the C library for Linux, we provide some extra definitions which only apply on those systems. These are noted in this section.

A.1. Linux-specific C type sizes and alignments

The following definitions apply for all ABIs defined in this document. Here there is no differentiation between ILP32 and LP64 ABIs.

<table>
<thead>
<tr>
<th>Type</th>
<th>Size (Bytes)</th>
<th>Alignment (Bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>wchar_t</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>wint_t</td>
<td>4</td>
<td>4</td>
</tr>
</tbody>
</table>

A.2. Linux-specific C type representations

The following definitions apply for all ABIs defined in this document. Here there is no differentiation between ILP32 and LP64 ABIs.

wchar_t is signed. wint_t is unsigned.
RISC-V ELF Specification
Chapter 5. Code models

The RISC-V architecture constrains the addressing of positions in the address space. There is no single instruction that can refer to an arbitrary memory position using a literal as its argument. Rather, instructions exist that, when combined together, can then be used to refer to a memory position via its literal. And, when not, other data structures are used to help the code to address the memory space. The coding conventions governing their use are known as code models.

However, some code models can't access the whole address space. The linker may raise an error if it cannot adjust the instructions to access the target address in the current code model.

5.1. Medium low code model

The medium low code model, or medlow, allows the code to address the whole RV32 address space or the lower 2 GiB and highest 2 GiB of the RV64 address space (0xFFFFF7FFFFF800 ~ 0xFFFFFFFFFFFFFFFF and 0x0 ~ 0x00000007FFFFF7FF). By using the lui and load / store instructions, when referring to an object, or addi, when calculating an address literal, for example, a 32-bit address literal can be produced.

The following instructions show how to load a value, store a value, or calculate an address in the medlow code model.

```assembly
# Load value from a symbol
lui a0, %hi(symbol)
lw a0, %lo(symbol)(a0)

# Store value to a symbol
lui a0, %hi(symbol)
sw a1, %lo(symbol)(a0)

# Calculate address
lui a0, %hi(symbol)
addi a0, a0, %lo(symbol)
```

The ranges on RV64 are not 0x0 ~ 0x00000007FFFFF and 0xFFFFF80000000 ~ 0xFFFFFFFFFFFF due to RISC-V's sign-extension of immediates; the following code fragments show where the ranges come from:

```assembly
# Largest postive number:
lui a0, 0x7fff # a0 = 0x7fff000
addi a0, 0x7ff # a0 = a0 + 2047 = 0x00000007FFFFF7FF

# Smallest negative number:
lui a0, 0x800000 # a0 = 0xffffffff80000000
addi a0, a0, -0x800 # a0 = a0 + -2048 = 0xFFFFF7FFFF800
```
5.2. Medium any code model

The medium any code model, or medany, allows the code to address the range between -2 GiB and +2 GiB from its position. By using auipc and load / store instructions, when referring to an object, or addi, when calculating an address literal, for example, a signed 32-bit offset, relative to the value of the pc register, can be produced.

As a special edge-case, undefined weak symbols must still be supported, whose addresses will be 0 and may be out of range depending on the address at which the code is linked. Any references to possibly-undefined weak symbols should be made indirectly through the GOT as is used for position-independent code. Not doing so is deprecated and a future version of this specification will require using the GOT, not just advise.

This is not yet a requirement as existing toolchains predating this part of the specification do not adhere to this, and without improvements to linker relaxation support doing so would regress performance and code size.

The following instructions show how to load a value, store a value, or calculate an address in the medany code model.

```assembly
# Load value from a symbol
.Ltmp0:  auipc a0, %pcrel_hi(symbol)
        lw    a0, %pcrel_lo(.Ltmp0)(a0)

# Store value to a symbol
.Ltmp1:  auipc a0, %pcrel_hi(symbol)
        sw    a1, %pcrel_lo(.Ltmp1)(a0)

# Calculate address
.Ltmp2:  auipc a0, %pcrel_hi(symbol)
        addi  a0, a0, %pcrel_lo(.Ltmp2)
```

Although the generated code is technically position independent, it’s not suitable for ELF shared libraries due to differing symbol interposition rules; for that, please use the medium position independent code model below.

5.3. Medium position independent code model

This model is similar to the medium any code model, but uses the global offset table (GOT) for non-local symbol addresses.

```assembly
# Load value from a local symbol
.Ltmp0:  auipc a0, %pcrel_hi(symbol)
        lw    a0, %pcrel_lo(.Ltmp0)(a0)

# Store value to a local symbol
.Ltmp1:  auipc a0, %pcrel_hi(symbol)
```
sw a1, %pcrel_lo(.Ltmp1)(a0)

# Calculate address of a local symbol
.Ltmp2:    auipc a0, %pcrel_hi(symbol)
            addi a0, a0, %pcrel_lo(.Ltmp2)

# Calculate address of non-local symbol
.Ltmp3:    auipc a0, %got_pcrel_hi(symbol)
            l[w|d] a0, a0, %pcrel_lo(.Ltmp3)
Chapter 6. Dynamic Linking

Any functions that use registers in a way that is incompatible with the calling convention of the ABI in use must be annotated with `STO_RISCV_VARIANT_CC`, as defined in Section 8.3.

Vector registers have a variable size depending on the hardware implementation and can be quite large. Saving/restoring all these vector arguments in a run-time linker's lazy resolver would use a large amount of stack space and hurt performance. `STO_RISCV_VARIANT_CC` attribute will require the run-time linker to resolve the symbol directly to prevent saving/restoring any vector registers.
Chapter 7. C++ Name Mangling

C++ name mangling for RISC-V follows the Itanium C++ ABI [itanium-cxx-abi]; there are no RISC-V specific mangling rules.

See the "Type encodings" section in Itanium C++ ABI for more detail on how to mangle types.
Chapter 8. ELF Object Files

The ELF object file format for RISC-V follows the *Generic System V Application Binary Interface [gabi]* ("gABI"); this specification only describes RISC-V-specific definitions.

8.1. File Header

The section below lists the defined RISC-V-specific values for several ELF header fields; any fields not listed in this section have no RISC-V-specific values.

e_ident

**EI_CLASS**

Specifies the base ISA, either RV32 or RV64. Linking RV32 and RV64 code together is not supported.

- **ELFCLASS64** ELF-64 Object File
- **ELFCLASS32** ELF-32 Object File

**EI_DATA**

Specifies the endianness; either big-endian or little-endian. Linking big-endian and little-endian code together is not supported.

- **ELFDATA2LSB** Little-endian Object File
- **ELFDATA2MSB** Big-endian Object File

e_machine

Identifies the machine this ELF file targets. Always contains EM_RISCV (243) for RISC-V ELF files.

e_flags

Describes the format of this ELF file. These flags are used by the linker to disallow linking ELF files with incompatible ABIs together, *Table 7* shows the layout of e_flags, and flag details are listed below.

*Table 7. Layout of e_flags*

<table>
<thead>
<tr>
<th>Bit 0</th>
<th>Bits 1 - 2</th>
<th>Bit 3</th>
<th>Bit 4</th>
<th>Bits 5 - 23</th>
<th>Bits 24 - 31</th>
</tr>
</thead>
<tbody>
<tr>
<td>RVC</td>
<td>Float ABI</td>
<td>RVE</td>
<td>TSO</td>
<td>Reserved</td>
<td>Non-standard extensions</td>
</tr>
</tbody>
</table>

**EF_RISCV_RVC (0x0001)**

This bit is set when the binary targets the C ABI, which allows instructions to be aligned to 16-bit boundaries (the base RV32 and RV64 ISAs only allow 32-bit instruction alignment). When linking objects which specify EF_RISCV_RVC, the linker is permitted to use RVC instructions such as C jal in the linker relaxation process.

**EF_RISCV_FLOAT_ABI_SOFT (0x0000)**
EF_RISCV_FLOAT_ABI_SINGLE (0x0002)

EF_RISCV_FLOAT_ABI_DOUBLE (0x0004)

EF_RISCV_FLOAT_ABI_QUAD (0x0006)
These flags identify the floating point ABI in use for this ELF file. They store the largest floating-point type that ends up in registers as part of the ABI (but do not control if code generation is allowed to use floating-point internally). The rule is that if you have a floating-point type in a register, then you also have all smaller floating-point types in registers. For example _DOUBLE would store "float" and "double" values in F registers, but would not store "long double" values in F registers. If none of the float ABI flags are set, the object is taken to use the soft-float ABI.

EF_RISCV_FLOAT_ABI (0x0006)
This macro is used as a mask to test for one of the above floating-point ABIs, e.g., \((e\_flags \& EF_RISCV_FLOAT_ABI) == EF_RISCV_FLOAT_ABI_DOUBLE\).

EF_RISCV_RVE (0x0008)
This bit is set when the binary targets the E ABI.

EF_RISCV_TSO (0x0010)
This bit is set when the binary requires the RVTSO memory consistency model.

Until such a time that the Reserved bits (0x00ffffffe0) are allocated by future versions of this specification, they shall not be set by standard software. Non-standard extensions are free to use bits 24-31 for any purpose. This may conflict with other non-standard extensions.

There is no provision for compatibility between conflicting uses of the e_flags bits reserved for non-standard extensions, and many standard RISC-V tools will ignore them. Do not use them unless you control both the toolchain and the operating system, and the ABI differences are so significant they cannot be done with a .RISCV.attributes tag nor an ELF note, such as using a different syscall ABI.

==== Policy for Merge Objects With Different File Headers
This section describe the behavior when the inputs files come with different file headers.

\textbf{e\_ident} and \textbf{e\_machine} should have exact same value otherwise linker should raise an error.

\textbf{e\_flags} has different different policy for different fields:

\textbf{RVC}
Input file could have different values for the RVC field; the linker should set this field into EF_RISCV_RVC if any of the input objects has been set.

\textbf{Float ABI}
Linker should report errors if object files of different value for float ABI field.
RVE
Linker should report errors if object files of different value for RVE field.

TSO
Linker should report errors if object files of different value for TSO field.

The static linker may ignore the compatibility checks if all fields in the `e_flags` are zero and all sections in the input file are non-executable sections.

8.2. String Tables
There are no RISC-V specific definitions relating to ELF string tables.

8.3. Symbol Table

`st_other`

The lower 2 bits are used to specify a symbol’s visibility. The remaining 6 bits have no defined meaning in the ELF gABI. We use the highest bit to mark functions that do not follow the standard calling convention for the ABI in use.

The defined processor-specific `st_other` flags are listed in Table 8.

Table 8. RISC-V-specific `st_other` flags

<table>
<thead>
<tr>
<th>Name</th>
<th>Mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>STO_RISCV_VARIANT_CC</td>
<td>0x80</td>
</tr>
</tbody>
</table>

See Chapter 6 for the meaning of `STO_RISCV_VARIANT_CC`.

`__global_pointer$` must be exported in the dynamic symbol table of dynamically-linked executables if there are any GP-relative accesses present in the executable.

8.4. Relocations

RISC-V is a classical RISC architecture that has densely packed non-word sized instruction immediate values. While the linker can make relocations on arbitrary memory locations, many of the RISC-V relocations are designed for use with specific instructions or instruction sequences. RISC-V has several instruction specific encodings for PC-Relative address loading, jumps, branches and the RVC compressed instruction set.

The purpose of this section is to describe the RISC-V specific instruction sequences with their associated relocations in addition to the general purpose machine word sized relocations that are used for symbol addresses in the Global Offset Table or DWARF meta data.

Table 9 provides details of the RISC-V ELF relocations; the meaning of each column is given below:

**Enum**

The number of the relocation, encoded in the `r_info` field
**ELF Reloc Type**

The name of the relocation, omitting the prefix of `R_RISCV_`.

**Type**

Whether the relocation is a static or dynamic relocation:

- A static relocation relocates a location in a relocatable file, processed by a static linker.
- A dynamic relocation relocates a location in an executable or shared object, processed by a run-time linker.
- **Both**: Some relocation types are used by both static relocations and dynamic relocations.

**Field**

Describes the set of bits affected by this relocation; see Section 8.4.2 for the definitions of the individual types

**Calculation**

Formula for how to resolve the relocation value; definitions of the symbols can be found in Section 8.4.1

**Description**

Additional information about the relocation

---

</tbody>
</table>

Nonstandard extensions are free to use relocation numbers 192-255 for any purpose. These relocations may conflict with other nonstandard extensions.

This section and later ones contain fragments written in assembler. The precise assembler syntax, including that of the relocations, is described in the *RISC-V Assembly Programmer’s Manual* [rv-asm].
8.4.1. Calculation Symbols

Table 10 provides details on the variables used in relocation calculation:

Table 10. Variables used in relocation calculation

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Addend field in the relocation entry associated with the symbol</td>
</tr>
<tr>
<td>B</td>
<td>Base address of a shared object loaded into memory</td>
</tr>
<tr>
<td>G</td>
<td>Offset of the symbol into the GOT (Global Offset Table)</td>
</tr>
<tr>
<td>GOT</td>
<td>Address of the GOT (Global Offset Table)</td>
</tr>
<tr>
<td>P</td>
<td>Position of the relocation</td>
</tr>
<tr>
<td>S</td>
<td>Value of the symbol in the symbol table</td>
</tr>
<tr>
<td>V</td>
<td>Value at the position of the relocation</td>
</tr>
<tr>
<td>GP</td>
<td>Value of <code>__global_pointer$</code> symbol</td>
</tr>
<tr>
<td>TLSMODULE</td>
<td>TLS module index for the object containing the symbol</td>
</tr>
<tr>
<td>TLSOFFSET</td>
<td>TLS static block offset (relative to <code>tp</code>) for the object containing the symbol</td>
</tr>
</tbody>
</table>

Global Pointer: It is assumed that program startup code will load the value of the `__global_pointer$` symbol into register `gp` (aka `x3`).

8.4.2. Field Symbols

Table 11 provides details on the variables used in relocation fields:

Table 11. Variables used in relocation fields

<table>
<thead>
<tr>
<th>Variable</th>

<td>Specifies a field as the immediate field in an S-type instruction</td>
</tr>
<tr>
<td>U-Type</td>
<td>Specifies a field as the immediate field in an U-type instruction</td>
</tr>
</tbody>
</table>

### 8.4.3. Constants

Table 12 provides details on the constants used in relocation fields:

**Table 12. Constants used in relocation fields**

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS_DTV_OFFSET</td>
<td>0x800</td>
</tr>
</tbody>
</table>

### 8.4.4. Absolute Addresses

32-bit absolute addresses in position dependent code are loaded with a pair of instructions which have an associated pair of relocations: \( R_{RISCV\_HI20} \) plus \( R_{RISCV\_LO12\_I} \) or \( R_{RISCV\_LO12\_S} \).

The \( R_{RISCV\_HI20} \) refers to an \texttt{LUI} instruction containing the high 20-bits to be relocated to an absolute symbol address. The \texttt{LUI} instruction is used in conjunction with one or more I-Type instructions (add immediate or load) with \( R_{RISCV\_LO12\_I} \) relocations or S-Type instructions (store) with \( R_{RISCV\_LO12\_S} \) relocations. The addresses for pair of relocations are calculated like this:

\[
\begin{align*}
\text{HI20} & \quad \text{symbol address + 0x800} >> 12 \\
\text{LO12} & \quad \text{symbol address}
\end{align*}
\]

The following assembly and relocations show loading an absolute address:

\begin{verbatim}
lui a0, %hi(symbol)  # R_{RISCV\_HI20} (symbol)  
addi a0, a0, %lo(symbol) # R_{RISCV\_LO12\_I} (symbol)
\end{verbatim}

### 8.4.5. Global Offset Table

For position independent code in dynamically linked objects, each shared object contains a GOT (Global Offset Table), which contains addresses of global symbols (objects and functions) referred to by the dynamically linked shared object. The GOT in each shared library is filled in by the dynamic linker during program loading, or on the first call to extern functions.

To avoid dynamic relocations within the text segment of position independent code the GOT is used for indirection. Instead of code loading virtual addresses directly, as can be done in static code, addresses are loaded from the GOT. This allows runtime binding to external objects and functions at the expense of a slightly higher runtime overhead for access to extern objects and functions.
8.4.6. Program Linkage Table

The PLT (Program Linkage Table) exists to allow function calls between dynamically linked shared objects. Each dynamic object has its own GOT (Global Offset Table) and PLT (Program Linkage Table).

The first entry of a shared object PLT is a special entry that calls \_dl\_runtime\_resolve to resolve the GOT offset for the called function. The \_dl\_runtime\_resolve function in the dynamic loader resolves the GOT offsets lazily on the first call to any function, except when \_LD\_BIND\_NOW is set in which case the GOT entries are populated by the dynamic linker before the executable is started. Lazy resolution of GOT entries is intended to speed up program loading by deferring symbol resolution to the first time the function is called. The first entry in the PLT occupies two 16 byte entries:

```
1:  auipc  t2, %pcrel_hi(.got.plt)
    sub   t1, t1, t3               # shifted .got.plt offset + hdr size + 12
    l[w|d] t3, %pcrel_lo(1b)(t2)   # _dl_runtime_resolve
    addi  t1, t1, -(hdr size + 12) # shifted .got.plt offset
    addi  t0, t2, %pcrel_lo(1b)    # &.got.plt
    srli  t1, t1, log2(16/PTRSIZE) # .got.plt offset
    l[w|d] t0, PTRSIZE(t0)          # link map
    jr     t3
```

Subsequent function entry stubs in the PLT take up 16 bytes and load a function pointer from the GOT. On the first call to a function, the entry redirects to the first PLT entry which calls \_dl\_runtime\_resolve and fills in the GOT entry for subsequent calls to the function:

```
1:  auipc  t3, %pcrel_hi(function@.got.plt)
    l[w|d] t3, %pcrel_lo(1b)(t3)
    jalr  t1, t3
    nop
```

8.4.7. Procedure Calls

\_R\_RISCV\_CALL and \_R\_RISCV\_CALL\_PLT relocations are associated with pairs of instructions (AUIPC+JALR) generated by the CALL or TAIL pseudoinstructions. Originally, these relocations had slightly different behavior, but that has turned out to be unnecessary, and they are now interchangeable, \_R\_RISCV\_CALL is deprecated, suggest using \_R\_RISCV\_CALL\_PLT instead.

With linker relaxation enabled, the AUIPC instruction in the AUIPC+JALR pair has both a \_R\_RISCV\_CALL or \_R\_RISCV\_CALL\_PLT relocation and an \_R\_RISCV\_RELAX relocation indicating the instruction sequence can be relaxed during linking.

Procedure call linker relaxation allows the AUIPC+JALR pair to be relaxed to the JAL instruction when the procedure or PLT entry is within (-1MiB to +1MiB-2) of the instruction pair.

The pseudoinstruction:
call symbol
call symbol@plt

expands to the following assembly and relocation:

```
auipc ra, 0           # R_RISCV_CALL (symbol), R_RISCV_RELAX (symbol)
jalr  ra, ra, 0
```

and when symbol has an @plt suffix it expands to:

```
auipc ra, 0           # R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX (symbol)
jalr  ra, ra, 0
```

8.4.8. PC-Relative Jumps and Branches

Unconditional jump (J-Type) instructions have a R_RISCV_JAL relocation that can represent an even signed 21-bit offset (-1MiB to +1MiB-2).

Branch (SB-Type) instructions have a R_RISCV_BRANCH relocation that can represent an even signed 13-bit offset (-4096 to +4094).

8.4.9. PC-Relative Symbol Addresses

32-bit PC-relative relocations for symbol addresses on sequences of instructions such as the AUIPC+ADDI instruction pair expanded from the la pseudoinstruction, in position independent code typically have an associated pair of relocations: R_RISCV_PCREL_HI20 plus R_RISCV_PCREL_LO12_I or R_RISCV_PCREL_LO12_S.

The R_RISCV_PCREL_HI20 relocation refers to an AUIPC instruction containing the high 20-bits to be relocated to a symbol relative to the program counter address of the AUIPC instruction. The AUIPC instruction is used in conjunction with one or more I-Type instructions (add immediate or load) with R_RISCV_PCREL_LO12_I relocations or S-Type instructions (store) with R_RISCV_PCREL_LO12_S relocations.

The R_RISCV_PCREL_LO12_I or R_RISCV_PCREL_LO12_S relocations contain a label pointing to an instruction in the same section with an R_RISCV_PCREL_HI20 relocation entry that points to the target symbol:

- At label: R_RISCV_PCREL_HI20 relocation entry → symbol
- R_RISCV_PCREL_LO12_I relocation entry → label

To get the symbol address to perform the calculation to fill the 12-bit immediate on the add, load or store instruction the linker finds the R_RISCV_PCREL_HI20 relocation entry associated with the AUIPC instruction. The addresses for pair of relocations are calculated like this:
The successive instruction has a signed 12-bit immediate so the value of the preceding high 20-bit relocation may have 1 added to it.

Note the compiler emitted instructions for PC-relative symbol addresses are not necessarily sequential or in pairs. There is a constraint that the instruction with the R_RISCV_PCREL_LO12_I or R_RISCV_PCREL_LO12_S relocation label points to a valid HI20 PC-relative relocation pointing to the symbol.

Here is example assembler showing the relocation types:

```
label:
    auipc t0, %pcrel_hi(symbol)   # R_RISCV_PCREL_HI20 (symbol)
lui t1, 1
    lw t2, t0, %pcrel_lo(label)   # R_RISCV_PCREL_LO12_I (label)
    add t2, t2, t1
    sw t2, t0, %pcrel_lo(label)   # R_RISCV_PCREL_LO12_S (label)
```

### 8.4.10. Relocation for Alignment

The relocation type R_RISCV_ALIGN marks a location that must be aligned to N-bytes, where N is the smallest power of two that is greater than the value of the addend field, e.g. R_RISCV_ALIGN with addend value 2 means align to 4 bytes, R_RISCV_ALIGN with addend value 4 means align to 8 bytes; this relocation is only required if the containing section has any R_RISCV_RELAX relocations, R_RISCV_ALIGN points to the beginning of the padding bytes, and the instruction that actually needs to be aligned is located at the point of R_RISCV_ALIGN plus its addend.

To ensure the linker can always satisfy the required alignment solely by deleting bytes, the compiler or assembler must emit a R_RISCV_ALIGN relocation and then insert N - [IALIGN] padding bytes before the location where we need to align, it could be mark by an alignment directive like .align, .p2align or .balign or emit by compiler directly, the addend value of that relocation is the number of padding bytes.

The compiler and assembler must ensure padding bytes are valid instructions without any side-effect like nop or c.nop, and make sure those instructions are aligned to IALIGN if possible.

The linker may remove part of the padding bytes at the linking process to meet the alignment requirement, and must make sure those padding bytes still are valid instructions and each instruction is aligned to at least IALIGN byte.

Here is example to showing how R_RISCV_ALIGN is used:

```
0x0    c.nop           # R_RISCV_ALIGN with addend 2
0x2    add t1, t2, t3  # This instruction must align to 4 byte.
```
**R_RISCV_ALIGN** relocation is needed because linker relaxation can shrink preceding code during the linking process, which may cause an aligned location to become mis-aligned.

IALIGN means the instruction-address alignment constraint. IALIGN is 4 bytes in the base ISA, but some ISA extensions, including the compressed ISA extension, relax IALIGN to 2 bytes. IALIGN may not take on any value other than 4 or 2. This term is also defined in *The RISC-V Instruction Set Manual* with a similar meaning, the only difference being it is specified in terms of the number of bits instead of the number of bytes.

Here is pseudocode to decide the alignment of **R_RISCV_ALIGN** relocation:

```python
# input:
#   addend: addend value of relocation with **R_RISCV_ALIGN** type.
# output:
#   Alignment of this relocation.

def align(addend):
    ALIGN = 1
    while addend >= ALIGN:
        ALIGN *= 2
    return ALIGN
```

### 8.5. Thread Local Storage

RISC-V adopts the ELF Thread Local Storage Model in which ELF objects define .tbss and .tdata sections and PT_TLS program headers that contain the TLS "initialization images" for new threads. The .tbss and .tdata sections are not referenced directly like regular segments, rather they are copied or allocated to the thread local storage space of newly created threads. See *ELF Handling For Thread-Local Storage* [tls].

In The ELF Thread Local Storage Model, TLS offsets are used instead of pointers. The ELF TLS sections are initialization images for the thread local variables of each new thread. A TLS offset defines an offset into the dynamic thread vector which is pointed to by the TCB (Thread Control Block). RISC-V uses Variant I as described by the ELF TLS specification, with **tp** containing the address one past the end of the TCB.

There are various thread local storage models for statically allocated or dynamically allocated thread local storage. *Table 13* lists the thread local storage models:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Model</th>
<th>TLS LE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Exec</td>
<td>TLS IE</td>
<td>Initial Exec</td>
</tr>
</tbody>
</table>
The program linker in the case of static TLS or the dynamic linker in the case of dynamic TLS allocate TLS offsets for storage of thread local variables.

Global Dynamic model is also known as General Dynamic model.

### 8.5.1. Local Exec

Local exec is a form of static thread local storage. This model is used when static linking as the TLS offsets are resolved during program linking.

**Variable attribute**

```c
__thread int i __attribute__((tls_model("local-exec")));  
```

Example assembler load and store of a thread local variable `i` using the `%tprel_hi`, `%tprel_add` and `%tprel_lo` assembler functions. The emitted relocations are in comments.

```asm
lui a5,%tprel_hi(i)           # R_RISCV_TPREL_HI20 (symbol)
add a5,a5,tp,%tprel_add(i)    # R_RISCV_TPREL_ADD (symbol)
lw  t0,%tprel_lo(i)(a5)       # R_RISCV_TPREL_LO12_I (symbol)
addi t0,t0,1
sw  t0,%tprel_lo(i)(a5)       # R_RISCV_TPREL_LO12_S (symbol)
```

The `%tprel_add` assembler function does not return a value and is used purely to associate the `R_RISCV_TPREL_ADD` relocation with the `add` instruction.

### 8.5.2. Initial Exec

Initial exec is a form of static thread local storage that can be used in shared libraries that use thread local storage. TLS relocations are performed at load time. `dlopen` calls to libraries that use thread local storage may fail when using the initial exec thread local storage model as TLS offsets must all be resolved at load time. This model uses the GOT to resolve TLS offsets.

**Variable attribute**

```c
__thread int i __attribute__((tls_model("initial-exec")));  
```

**ELF flags**

```
DF_STATIC_TLS
```

Example assembler load and store of a thread local variable `i` using the `la.tls.ie` pseudoinstruction, with the emitted TLS relocations in comments:

```asm
la.tls.ie a5,i
add a5,a5,tp
```
lw  t0,0(a5)
addi t0,t0,1
sw  t0,0(a5)

The assembler pseudoinstruction:

la.tls.ie a5,symbol

expands to the following assembly instructions and relocations:

label:
  auipc a5, 0                   # R_RISCV_TLS_GOT_HI20 (symbol)
  {ld,lw} a5, 0(a5)             # R_RISCV_PCREL_LO12_I (label)

8.5.3. Global Dynamic

RISC-V local dynamic and global dynamic TLS models generate equivalent object code. The Global dynamic thread local storage model is used for PIC Shared libraries and handles the case where more than one library uses thread local variables, and additionally allows libraries to be loaded and unloaded at runtime using dlopen. In the global dynamic model, application code calls the dynamic linker function __tls_get_addr to locate TLS offsets into the dynamic thread vector at runtime.

Variable attribute

__thread int i __attribute__((tls_model("global-dynamic")));

Example assembler load and store of a thread local variable i using the la.tls.gd pseudoinstruction, with the emitted TLS relocations in comments:

la.tls.gd a0,i
  call  __tls_get_addr@plt
  mv   a5,a0
  lw   t0,0(a5)
  addi t0,t0,1
  sw   t0,0(a5)

The assembler pseudoinstruction:

la.tls.gd a0,symbol

expands to the following assembly instructions and relocations:

label:
  auipc a0,0                    # R_RISCV_TLS_GD_HI20 (symbol)
In the Global Dynamic model, the runtime library provides the `__tls_get_addr` function:

```c
extern void *__tls_get_addr (tls_index *ti);
```

where the type `tls_index` is defined as:

```c
typedef struct {
    unsigned long int ti_module;
    unsigned long int ti_offset;
} tls_index;
```

### 8.6. Sections

#### 8.6.1. Section Types

The defined processor-specific section types are listed in Table 14.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHT_RISCV_ATTRIBUTES</td>
<td>0x70000003</td>
<td>none</td>
</tr>
</tbody>
</table>

#### 8.6.2. Special Sections

Table 15 lists the special sections defined by this ABI.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>.riscv.attributes</td>
<td>SHT_RISCV_ATTRIBUTES</td>
<td>none</td>
</tr>
</tbody>
</table>

`.riscv.attributes` names a section that contains RISC-V ELF attributes.

### 8.7. Program Header Table

The defined processor-specific segment types are listed in Table 16.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PT_RISCV_ATTRIBUTES</td>
<td>0x70000003</td>
<td>RISC-V ELF attribute section.</td>
</tr>
</tbody>
</table>
PT_RISCV_ATTRIBUTES describes the location of RISC-V ELF attribute section.

8.8. Note Sections

There are no RISC-V specific definitions relating to ELF note sections.

8.9. Dynamic Section

The defined processor-specific dynamic array tags are listed in Table 17.

Table 17. RISC-V-specific dynamic array tags

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>d_un</th>
<th>Executable</th>
<th>Shared Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>DT_RISCV_VARIANT_CC</td>
<td>0x70000001</td>
<td>d_val</td>
<td>Platform specific</td>
<td>Platform specific</td>
</tr>
</tbody>
</table>

An object must have the dynamic tag DT_RISCV_VARIANT_CC if it has one or more R_RISCV_JUMP_SLOT relocations against symbols with the STO_RISCV_VARIANT_CC attribute.

DT_INIT and DT_FINI are not required to be supported and should be avoided in favour of DT_PREINIT_ARRAY, DT_INIT_ARRAY and DT_FINI_ARRAY.

8.10. Hash Table

There are no RISC-V specific definitions relating to ELF hash tables.

8.11. Attributes

Attributes are used to record information about an object file-binary that a linker or runtime loader needs to check compatibility.

Attributes are encoded in a vendor-specific section of type SHT_RISCV_ATTRIBUTES and name .riscv.attributes. The value of an attribute can hold an integer encoded in the uleb128 format or a null-terminated byte string (NTBS).

RISC-V attributes have a string value if the tag number is odd and an integer value if the tag number is even.

8.11.1. List of attributes

Table 18. RISC-V attributes

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
<th>Parameter type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tag_RISCV_stack_align</td>
<td>4</td>
<td>uleb128</td>
<td>Indicates the stack alignment requirement in bytes.</td>
</tr>
<tr>
<td>Tag_RISCV_arch</td>
<td>5</td>
<td>NTBS</td>
<td>Indicates the target architecture of this object.</td>
</tr>
<tr>
<td>Tag</td>
<td>Value</td>
<td>Parameter type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------</td>
<td>----------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Tag_RISCV_unaligned_access</td>
<td>6</td>
<td>uleb128</td>
<td>Indicates whether to impose unaligned memory accesses in code generation.</td>
</tr>
<tr>
<td>Tag_RISCV_priv_spec</td>
<td>8</td>
<td>uleb128</td>
<td>Deprecated, indicates the major version of the privileged specification.</td>
</tr>
<tr>
<td>Tag_RISCV_priv_spec_minor</td>
<td>10</td>
<td>uleb128</td>
<td>Deprecated, indicates the minor version of the privileged specification.</td>
</tr>
<tr>
<td>Tag_RISCV_priv_spec_revision</td>
<td>12</td>
<td>uleb128</td>
<td>Deprecated, indicates the revision version of the privileged specification.</td>
</tr>
<tr>
<td>Reserved for non-standard attribute</td>
<td>32768</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

**8.11.2. Detailed attribute description**

**How does this specification describe public attributes?**

Each attribute is described in the following structure: `<Tag name>, <Value>, <Parameter type 1>=<Parameter name 1>, <Parameter type 2>=<Parameter name 2>`

**Tag_RISCV_stack_align, 4, uleb128=value**

Tag_RISCV_stack_align records the N-byte stack alignment for this object. The default value is 16 for RV32I or RV64I, and 4 for RV32E.

**Merge Policy**

The linker should report errors if link object files with different Tag_RISCV_stack_align values.

**Tag_RISCV_arch, 5, NTBS=subarch**

Tag_RISCV_arch contains a string for the target architecture taken from the option `-march`. Different architectures will be integrated into a superset when object files are merged.

Tag_RISCV_arch should be recorded in lowercase, and all extensions should be separated by underline(_).

Note that the version information for target architecture must be presented explicitly in the attribute and abbreviations must be expanded. The version information, if not given by `-march`, must agree with the default specified by the tool. For example, the architecture `rv32i` has to be recorded in the attribute as `rv32i2p1` in which `2p1` stands for the default version of its based ISA. On the other hand, the architecture `rv32g` has to be presented as `rv32i2p1_m2p0_a2p1_f2p2_d2p2_zicsr2p0_zifencei2p0` in which the abbreviation `g` is expanded to the `imafd_zicsr_zifencei` combination with default versions of the standard extensions.
The toolchain should normalized the architecture string into canonical order which defined in *The RISC-V Instruction Set Manual, Volume I: User-Level ISA, Document [riscv-unpriv]*, expanded with all required extension and should add shorthand extension into architecture string if all expanded extensions are included in architecture string.

A shorthand extension is an extension that does not define any actual instructions, registers or behavior, but requires other extensions, such as the `zks` extension, which is defined in the cryptographic extension. `zks` extension is shorthand for `zbkb`, `zbkc`, `zbkx`, `zksed` and `zksh`, so the toolchain should normalize `rv32i_zbkb_zbkc_zbkx_zksed_zksh` to `rv32i_zbkb_zbkc_zbkx_zks_zksed_zksh`; `g` is an exception and does not apply to this rule.

**Merge Policy**

The linker should merge the different architectures into a superset when object files are merged, and should report errors if the merge result contains conflict extensions.

This specification does not mandate rules on how to merge ISA strings that refer to different versions of the same ISA extension. The suggested merge rules are as follows:

- Merge versions into the latest version of all input versions that are ratified without warning or error.
- The linker should emit a warning or error if input versions have different versions and any extension versions are not ratified.
- The linker may report a warning or error if it detects incompatible versions, even if it’s ratified.

Example of conflicting merge result: `RV32IF` and `RV32IZfinx` will be merged into `RV32IFZfinx`, which is an invalid architecture since `F` and `Zfinx` conflict.

**Tag_RISCV_unaligned_access, 6, uleb128=value**

`Tag_RISCV_unaligned_access` denotes the code generation policy for this object file. Its values are defined as follows:

- 0: This object does not perform any unaligned memory accesses.
- 1: This object may perform unaligned memory accesses.

**Merge policy**

Input file could have different values for the `Tag_RISCV_unaligned_access`; the linker should set this field into 1 if any of the input objects has been set.

**Tag_RISCV_priv_spec, 8, uleb128=version**

**Tag_RISCV_priv_spec_minor, 10, uleb128=version**
**Tag_RISCV_priv_spec_revision, 12, uleb128=version**

⚠️ Those three attributes are deprecated since RISC-V using extensions with version rather than a single privileged specification version scheme for privileged ISA.

Tag_RISCV_priv_spec contains the major/minor/revision version information of the privileged specification.

**Merge policy**

The linker should report errors if object files of different privileged specification versions are merged.
Chapter 9. Linker Relaxation

At link time, when all the memory objects have been resolved, the code sequence used to refer to them may be simplified and optimized by the linker by relaxing some assumptions about the memory layout made at compile time.

Some relocation types, in certain situations, indicate to the linker where this can happen. Additionally, some relocation types indicate to the linker the associated parts of a code sequence that can be thusly simplified, rather than to instruct the linker how to apply a relocation.

The linker should only perform such relaxations when a R_RISCV_RELAX relocation is at the same position as a candidate relocation.

As this transformation may delete bytes (and thus invalidate references that are commonly resolved at compile-time, such as intra-function jumps), code generators must in general ensure that relocations are always emitted when relaxation is enabled.

9.1. Linker Relaxation Types

The purpose of this section is to describe all types of linker relaxation, the linker may implement a part of linker relaxation type, and can be skipped the relaxation type is unsupported.

Each candidate relocation might fit more than one relaxation type, the linker should only apply one relaxation type.

In the linker relaxation optimization, we introduce a concept called relocation group; a relocation group consists of 1) relocations associated with the same target symbol and can be applied with the same relaxation, or 2) relocations with the linkage relationship (e.g. R_RISCV_PCREL_LO12_S linked with a R_RISCV_PCREL_HI20); all relocations in a single group must be present in the same section, otherwise will split into another relocation group.

Every relocation group must apply the same relaxation type, and the linker should not apply linker relaxation to only part of the relocation group.

Applying relaxation on the part of the relocation group might result in a wrong execution result; for example, a relocation group consists of lui t0, 0 # R_RISCV_HI20 (foo), lw t1, 0(t0) # R_RISCV_LO12_I (foo), and we only apply global pointer relaxation on first instruction, then remove that instruction, and didn’t apply relaxation on the second instruction, which made the load instruction reference to an unspecified address.

9.1.1. Function Call Relaxation

Target Relocation

R_RISCV_CALL, R_RISCV_CALL_PLT.

Description

This relaxation type can relax AUIPC+JALR into JAL.
**Condition**

The offset between the location of relocation and target symbol or the PLT stub of the target symbol is within +-1MiB.

**Relaxation**

- Instruction sequence associated with `R_RISCV_CALL` or `R_RISCV_CALL_PLT` can be rewritten to a single JAL instruction with the offset between the location of relocation and target symbol.

**Example**

Relaxation candidate:

```assembly
auipc ra, 0           # R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX
jalr  ra, ra, 0
```

Relaxation result:

```assembly
jal  ra, 0            # R_RISCV_JAL (symbol)
```

Using address of PLT stubs of the target symbol or address target symbol directly will resolve by linker according to the visibility of the target symbol.

### 9.1.2. Compressed Function Call Relaxation

**Target Relocation**

R_RISCV_CALL, R_RISCV_CALL_PLT.

**Description**

This relaxation type can relax `AUIPC+JALR` into `C.JAL` instruction sequence.

**Condition**

The offset between the location of relocation and target symbol or the PLT stub of the target symbol is within +-2KiB and rd operand of second instruction in the instruction sequence is `X1/RA` and if it is RV32.

**Relaxation**

- Instruction sequence associated with `R_RISCV_CALL` or `R_RISCV_CALL_PLT` can be rewritten to a single `C.JAL` instruction with the offset between the location of relocation and target symbol.

**Example**

Relaxation candidate:

```assembly
auipc ra, 0           # R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX
jalr  ra, ra, 0
```
9.1.3. Compressed Tail Call Relaxation

Target Relocation
R_RISCV_CALL, R_RISCV_CALL_PLT.

Description
This relaxation type can relax AUIPC+JALR into C.J instruction sequence.

Condition
The offset between the location of relocation and target symbol or the PLT stub of the target symbol is within +/-2KiB and rd operand of second instruction in the instruction sequence is X0.

Relaxation
• Instruction sequence associated with R_RISCV_CALL or R_RISCV_CALL_PLT can be rewritten to a single C.J instruction with the offset between the location of relocation and target symbol.

Example
Relaxation candidate:

```
auipc ra, 0           # R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX
jalr  x0, ra, 0
```

Relaxation result:
```
c.j  ra, <offset-between-pc-and-symbol>
```

9.1.4. Global-pointer Relaxation

Target Relocation
R_RISCV_HI20, R_RISCV_LO12_I, R_RISCV_LO12_S, R_RISCV_PCREL_HI20, R_RISCV_PCREL_LO12_I, R_RISCV_PCREL_LO12_S

Description
This relaxation type can relax a sequence of the load address of a symbol or load/store with a symbol reference into global-pointer-relative instruction.

Condition
Offset between global-pointer and symbol is within +/-2KiB, R_RISCV_PCREL_LO12_I and R_RISCV_PCREL_LO12_S resolved as indirect relocation pointer. It will always point to another
R_RISCV_PCREL_HI20 relocation, the symbol pointed by R_RISCV_PCREL_HI20 will be used in the offset calculation.

Relaxation

- Instruction associated with R_RISCV_HI20 or R_RISCV_PCREL_HI20 can be removed.
- Instruction associated with R_RISCV_LO12_I, R_RISCV_LO12_S, R_RISCV_PCREL_LO12_I or R_RISCV_PCREL_LO12_S can be replaced with a global-pointer-relative access instruction.

Example

Relaxation candidate:

```plaintext
lui t0, 0       # R_RISCV_HI20 (symbol), R_RISCV_RELAX
lw t1, 0(t0)    # R_RISCV_LO12_I (symbol), R_RISCV_RELAX
```

Relaxation result:

```plaintext
lw t1, <gp-offset-for-symbol>(gp)
```

The global-pointer refers to the address of the __global_pointer$ symbol, which is the content of gp register.

This relaxation requires the program to initialize the gp register with the address of __global_pointer$ symbol before accessing any symbol address, strongly recommended initialize gp at the beginning of the program entry function like _start, and code fragments of initialization must disable linker relaxation to prevent initialization instruction relaxed into a NOP-like instruction (e.g. mv gp, gp).

The global pointer is referred to as the global offset table pointer in many other targets, however, RISC-V uses PC-relative addressing rather than access GOT via the global pointer register (gp), so we use gp register to optimize code size and performance of the symbol accessing.

9.1.5. Zero-page Relaxation

Target Relocation

R_RISCV_HI20, R_RISCV_LO12_I, R_RISCV_LO12_S
Description
This relaxation type can relax a sequence of the load address of a symbol or load/store with a symbol reference into shorter instruction sequence if possible.

Condition
The symbol address located within $0x0 \sim 0x7ff$ or $0xffffffffffffffe800 \sim 0xffffffffffffffff$ for RV64 and $0xfffffffff800 \sim 0xffffffff$ for RV32.

Relaxation
- Instruction associated with $\text{R}_\text{RISCV}_\text{HI20}$ can be removed if the symbol address satisfies the x0-relative access.
- Instruction associated with $\text{R}_\text{RISCV}_\text{LO12_I}$ or $\text{R}_\text{RISCV}_\text{LO12_S}$ can be relaxed into x0-relative access.

Example
Relaxation candidate:

```
lui t0, 0       # R_RISCV_HI20 (symbol), R_RISCV_RELAX
lw t1, 0(t0)    # R_RISCV_LO12_I (symbol), R_RISCV_RELAX
```

Relaxation result:

```
lw t1, <address-of-symbol>(x0)
```

9.1.6. Compressed LUI Relaxation

Target Relocation
$\text{R}_\text{RISCV}_\text{HI20}, \text{R}_\text{RISCV}_\text{LO12_I}, \text{R}_\text{RISCV}_\text{LO12_S}$

Description
This relaxation type can relax a sequence of the load address of a symbol or load/store with a symbol reference into shorter instruction sequence if possible.

Condition
The symbol address can be presented by a $\text{C.LUI}$ plus an $\text{ADDI}$ or load / store instruction.

Relaxation
- Instruction associated with $\text{R}_\text{RISCV}_\text{HI20}$ can be replaced with $\text{C.LUI}$.
- Instruction associated with $\text{R}_\text{RISCV}_\text{LO12_I}$ or $\text{R}_\text{RISCV}_\text{LO12_S}$ should keep unchanged.

Example
Relaxation candidate:

```
lui t0, 0       # R_RISCV_HI20 (symbol), R_RISCV_RELAX
lw t1, 0(t0)    # R_RISCV_LO12_I (symbol), R_RISCV_RELAX
```
9.1.7. Thread-pointer Relaxation

Target Relocation

R_RISCV_TPREL_HI20, R_RISCV_TPREL_ADD, R_RISCV_TPREL_LO12_I, R_RISCV_TPREL_LO12_S.

Description

This relaxation type can relax a sequence of the load address of a symbol or load/store with a thread-local symbol reference into a thread-pointer-relative instruction.

Condition

Offset between thread-pointer and thread-local symbol is within ±2KiB.

Relaxation

- Instruction associated with R_RISCV_TPREL_HI20 or R_RISCV_TPREL_ADD can be removed.
- Instruction associated with R_RISCV_TPREL_LO12_I or R_RISCV_TPREL_LO12_S can be replaced with a thread-pointer-relative access instruction.

Example

Relaxation candidate:

```
lui t0, 0       # R_RISCV_TPREL_HI20 (symbol), R_RISCV_RELAX
add t0, t0, tp  # R_RISCV_TPREL_ADD (symbol), R_RISCV_RELAX
lw t1, 0(t0)    # R_RISCV_TPREL_LO12_I (symbol), R_RISCV_RELAX
```

Relaxation result:

```
lw t1, <tp-offset-for-symbol>(tp)
```

RISC-V DWARF Specification
Chapter 10. DWARF Debugging Format

The DWARF debugging format for RISC-V follows the standard DWARF specification; this specification only describes RISC-V-specific definitions.
Chapter 11. DWARF Register Numbers

The table below lists the mapping from DWARF register numbers to machine registers.

Table 19. DWARF register number encodings

<table>
<thead>
<tr>
<th>DWARF Number</th>
<th>Register Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 31</td>
<td>x0 - x31</td>
<td>Integer Registers</td>
</tr>
<tr>
<td>32 - 63</td>
<td>f0 - f31</td>
<td>Floating-point Registers</td>
</tr>
<tr>
<td>64</td>
<td></td>
<td>Alternate Frame Return Column</td>
</tr>
<tr>
<td>65 - 95</td>
<td></td>
<td>Reserved for future standard extensions</td>
</tr>
<tr>
<td>96 - 127</td>
<td>v0 - v31</td>
<td>Vector Registers</td>
</tr>
<tr>
<td>128 - 3071</td>
<td></td>
<td>Reserved for future standard extensions</td>
</tr>
<tr>
<td>3072 - 4095</td>
<td></td>
<td>Reserved for custom extensions</td>
</tr>
<tr>
<td>4096 - 8191</td>
<td></td>
<td>CSRs</td>
</tr>
</tbody>
</table>

The alternate frame return column is meant to be used when unwinding from signal handlers, and stores the address where the signal handler will return to.

The RISC-V specification defines a total of 4096 CSRs (see [riscv-priv]). Each CSR is assigned a DWARF register number corresponding to its specified CSR number plus 4096.
