

Bank Account Example

First we must define some basic global data types.

Basic data types: $[INT, STRING]$.

Then we can define the schema "Person". It will have two state variables (data): name and address.

<i>Person</i>
<i>name</i> : <i>STRING</i>
<i>address</i> : <i>STRING</i>

No constraints are needed here.

Our second schema is "Account". State variables (data): owner, balance.

<i>Account</i>
<i>owner</i> : <i>Person</i>
<i>balance</i> : <i>INT</i>
<i>balance</i> ≥ 0

We must define the constraint that balance cannot be negative.

The last state schema that we will define here is "Bank".

<i>Bank</i>
<i>ownership</i> : <i>Person</i> \leftrightarrow <i>Account</i>

The relation "ownership" defines a set of pairs (*person*, *account*). We allow one person to have multiple bank accounts.

Now we have to define schemas for two operations: withdraw and deposit.

<i>Withdraw</i>
Δ <i>Account</i>
<i>amount?</i> : <i>NAT</i>
<i>person?</i> : <i>Person</i>
<i>person?</i> = <i>owner</i>
<i>balance'</i> = <i>balance</i> - <i>amount</i>

Here, the condition *person?* = *owner* represents a precondition for the operation, and the expression *balance'* = *balance* - *amount* captures its effect.

The operation "deposit" can be defined in a similar way.

Concrete values (constants) may be defined using a schema like this:

<i>JoeDoe</i>
<i>Person</i>
<i>name</i> = <i>Joe Doe</i>
<i>address</i> = <i>New York</i>

We include the schema "Person", effectively reusing all the declared state variables.

Instance of the "Bank" schema:

<i>GoldmanSachs</i>
<i>Bank</i>
<i>ownership = {(JoeDoe, AccountJD)}</i>

We assume that "AccountJD" is an existing constant of the schema "Account".
