% Networking % Jiří Benc, Red Hat % Advanced Operating Systems, MFF UK

Scope

- focused on Linux
- using Linux terminology
- the principles are general

Assumption

- knowledge of OSI model
- understanding of packet structure
- basic understanding of TCP/IP
- understanding of I/O (DMA, IRQ)

User Point of View

- network interfaces
 - usually having name and numeric ID
 - can be assigned IP addresses
 - can be administratively enabled/disabled
- apps operate with IP addresses
 - but can specify an interface
- system tables
 - routing tables
 - neighbor tables
 - ...

Basic Packet Processing

```
NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow
IRQ handler \rightarrow schedule processing \rightarrow
packet descriptor \rightarrow
L2 \rightarrow L3 \rightarrow L4 \rightarrow
socket lookup \rightarrow socket queue \rightarrow app wakeup \rightarrow
app read \rightarrow data copy \rightarrow buffer release
```

. . .

app write \rightarrow data copy \rightarrow packet descriptor \rightarrow L4 \rightarrow L3 \rightarrow L2 \rightarrow

enqueue \rightarrow dequeue \rightarrow DMA descriptor \rightarrow DMA \rightarrow tx trigger \rightarrow NIC tx \rightarrow tx IRQ \rightarrow IRQ handler \rightarrow memory release

Driver Processing (rx)

NIC rx \rightarrow DMA

DMA Ring Buffers

- separate tx and rx buffers
- configured by the driver
- contains data and metadata

Driver Processing (rx)

NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow IRQ handler \rightarrow schedule processing

Interrupts

- IRQ handler in the driver
- bottom half scheduled
- packet fetched
- new DMA rx buffer allocated

Driver Processing (rx)

NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow IRQ handler \rightarrow schedule processing \rightarrow packet descriptor

Packet Descriptor

- allocated by the driver
- sk_buff in Linux, mbuf in BSD, etc.
- packet metadata

Packet Descriptor

- buffer pointer
- data start
- data length
- header pointers
- incoming/outgoing interface
- L3 protocol

- queue priority
- packet mark
- reference count
- offload fields
 - vlan tag
 - hash
 - checksum

• ...

Packet Descriptor

- buffer pointer
- data start ← allows pop/push
- data length
- header pointers
- incoming/outgoing interface
- L3 protocol
- queue priority
- packet mark
- reference count
- offload fields
 - vlan tag
 - hash
 - checksum
- ...

Kernel Processing (rx)

```
NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow
IRQ handler \rightarrow schedule processing \rightarrow
packet descriptor \rightarrow
L2
```

Entering the Network Stack

- driver calls helper functions for L2 processing
 - L3 protocol filled in
 - L2 header removed
- handed over to the core kernel

Kernel Processing (rx)

```
NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow
IRQ handler \rightarrow schedule processing \rightarrow
packet descriptor \rightarrow
L2
```

Common Handling

- taps on network interface (packet inspection)
- rx hooks (virtual interfaces)
- protocol-independent firewall

Kernel Processing (rx)

```
NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow
IRQ handler \rightarrow schedule processing \rightarrow
packet descriptor \rightarrow
L2 \rightarrow L3 \rightarrow L4
```

Protocol Layers

- L2 independent
- table of L3 handlers \rightarrow L3 protocol handler
- L3 header processed and removed
- per-L3 table of L4 handlers \rightarrow L4 protocol handler
- L4 header processed and removed

Kernel Processing (rx)

NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow IRQ handler \rightarrow schedule processing \rightarrow packet descriptor \rightarrow L2 \rightarrow L3

L3 - IP

- defragmentation
- routing decision
 - forwarding: skip to tx path
 - local delivery: continue up the stack
- IP firewall (various attachment points)

Kernel Processing (rx)

```
NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow
IRQ handler \rightarrow schedule processing \rightarrow
packet descriptor \rightarrow
```

```
\label{eq:L2} \begin{array}{l} \mathsf{L2} \rightarrow \mathsf{L3} \rightarrow \mathsf{L4} \rightarrow \\ \text{socket lookup} \rightarrow \text{socket queue} \rightarrow \text{app wakeup} \end{array}
```

L4 - TCP

- TCP state machine
- socket lookup
- socket enqueue (of the sk_buff)
- application woken up

Kernel Processing (rx)

```
NIC rx \rightarrow DMA \rightarrow rx IRQ \rightarrow
IRQ handler \rightarrow schedule processing \rightarrow
packet descriptor \rightarrow
L2 \rightarrow L3 \rightarrow L4 \rightarrow
socket lookup \rightarrow socket queue \rightarrow app wakeup \rightarrow
app read \rightarrow data copy \rightarrow buffer release
```

Application

- read() syscall
- packet copy
- sk_buff freed

Kernel Processing (tx)

app write \rightarrow data copy \rightarrow packet descriptor

Application

- write() syscall
- sk_buff allocation (for DMA)
- data copy

Kernel Processing (tx)

app write \rightarrow data copy \rightarrow packet descriptor \rightarrow L4 \rightarrow L3

Protocol Layers

- TCP header pushed
- IP header pushed
 - IP firewall
 - routing decision
 - fragmentation (MTU, PMTU)

Kernel Processing (tx)

app write \rightarrow data copy \rightarrow packet descriptor \rightarrow L4 \rightarrow L3 \rightarrow L2

Protocol Layers

- L2 header pushed
 - neighbor cache, ARP lookup
- may need to wait for neighbor resolution
 - put to a wait list
 - resumed by incoming ARP reply
 - timer assigned for timeout
 - ICMP signalled back on error

Kernel Processing (tx)

app write \rightarrow data copy \rightarrow packet descriptor \rightarrow L4 \rightarrow L3 \rightarrow L2 \rightarrow enqueue \rightarrow dequeue

Tx Queues

- packet classified and enqueued
- dequeued
 - based on queue discipline
 - sk_buff priority field
- passed to the driver

Driver Processing (tx)

```
app write \rightarrow data copy \rightarrow packet descriptor \rightarrow
L4 \rightarrow L3 \rightarrow L2 \rightarrow
enqueue \rightarrow dequeue \rightarrow
DMA descriptor \rightarrow DMA \rightarrow
tx trigger \rightarrow NIC tx
```

Pushing to the NIC

- added to tx DMA ring buffer
- signalled to the NIC

Driver Processing (tx)

app write \rightarrow data copy \rightarrow packet descriptor \rightarrow L4 \rightarrow L3 \rightarrow L2 \rightarrow enqueue \rightarrow dequeue \rightarrow DMA descriptor \rightarrow DMA \rightarrow tx trigger \rightarrow NIC tx \rightarrow tx IRQ \rightarrow IRQ handler \rightarrow memory release

Freeing Resources

- NIC signals transmit done
- buffer unmapped, sk_buff released
- counters incremented

Special Protocols

ICMP

- just another L4 protocol
- communicates back to IP
 - PMTU updates
 - route redirects etc.

ARP and ICMPv6

• neighbor discovery

Performance Matters!

Performance Problems

- packet length unknown in advance
 - DMA scatter-gather
 - complicates packet processing (fragmented data)
 - header pop may require realloc

Performance Problems

- header push requires realloc
 - reserve space (at the driver level)
 - still may get out of space

Performance Problems

• enqueueing before tx

- bufferbloat high latency, lattency jitter, failure of TPC congestion control
- smaller buffers, better queueing disciplines

Performance Problems

- shared resources
 - flow caches, defrag buffers, etc.
 - remotely DoSable!
 - global limits
 - Iocally DoSable
 - per-group limits (cgroups)

Bottlenecks

- stack processing is too heavy
 - aggregation of packets
 - processing whole flows
- interrupts are slow
 - busy polling under load
- reading memory is slow
 - checksum offloading

Checksum Offloading

- for tx, checksum on copy from user
- FCS is always calculated by the NIC
- IP header checksum calculation is cheap
- L4 checksum
 - on rx, the NIC verifies the checksum
 - on tx, the NIC computes and fills in the checksum
- some protocols use CRC instead (SCTP)

Busy Polling under Load (NAPI)

- on rx, turn off IRQs
- fetch packets up to a limit
- repeat until there are no packets left
- turn on IRQ

Aggregation

Rx Aggregation (GRO)

- needs multiple rx queues in NIC
 - configurable filters
- on rx, packets for the same flow from a NAPI batch are combined into a super-packet
 - \Rightarrow GRO depends on NAPI
 - need to dissect the packets
 - passes the stack as a single packet
 - need to be able to reconstruct the original packets
 - split on tx (GSO)

Aggregation

Tx Aggregation (GSO)

- on tx, a packet is split into smaller packets
 - TCP segmentation for TCP super-packets
 - offloaded to NIC (TSO)
 - $\bullet \quad \Rightarrow \mathsf{TSO} \text{ depends on checksum offloading}$
 - IP fragmentation for datagram protocols
 - done in software when needed

Virtual NICs

- a driver not backed up by a real hardware
- vlan interface
- tun/tap
- veth
- ...

Containers (Network Name Spaces)

- partitioning of the network stack
- TCP/IP:
 - isolated routing tables
 - \Rightarrow independent IP addresses
 - separate limits (subject to global limits)
- each network interface can be in a single name space only

Virtual Networks

- building blocks:
 - virtual interfaces
 - software bridges (even programmable)
 - containers (network name spaces)
 - VMs
 - tunnels

Virtual Networks

Offloading to Hardware

- packet classification and switching
- match/action tables
 - tc supporting match/action (and queues)
- SR-IOV switch

Other Bottlenecks

- data copy
 - zero copy
 - need to ensure security
 - tx: packet can be changed while in flight
 - rx: uninitialized data after packet end
 - resources problem: mem reclaim on rx
 - needs tx checksum offloading

Other Bottlenecks

- sk_buff allocation
 - a lot of mm tricks depending on use case
 - for some cases sk_buff may not be needed at all (L2 switching)

Other Bottlenecks

- too many features
 - generic OS
 - usually only a subset of features is needed
 - XDP and eBPF

Conclusion

- complex topic
- fast moving
- is there interest in a deep dive?
